Problem 1.

Calculate the threshold for the following photonuclear reactions:

- $^{12}\text{C}(\gamma, \text{n}^0)^{11}\text{C}$

- $^{53}\text{Cr}(\gamma, \text{n}^0)^{52}\text{Cr}$

- $^{105}\text{Pd}(\gamma, \text{n}^0)^{104}\text{Pd}$

- $^{183}\text{W}(\gamma, \text{n}^0)^{182}\text{W}$

- How do these thresholds compare with what you would expect for a typical binding energy of a nucleon in a nucleus?

Solution

Problem 2.   Anderson 7.4

Suppose a 140 keV photon undergoes photoelectric effect in a lead sheet with a K-shell electron.

- What is the kinetic energy liberated?

- If it is assumed that this is all photoelectron kinetic energy, calculate the electron momentum and the photon momentum and compare the two.

Solution

Problem 3.   Anderson 7.11

Given that the mass attenuation coefficient for ^{63}Cu is $0.474\,\text{m}^2/\text{kg}$ at $40\,\text{keV}$ (photoelectron dominates) and $0.0042\,\text{m}^2/\text{kg}$ at $2\,\text{MeV}$ (incoherent scatter dominates), estimate the coefficient for ^{56}Fe at these energies.

Solution

Problem 4.

Go to the NIST XCOM webpage and find the photon energies where the photoelectric effect and Compton scattering (incoherent scattering) have the same magnitudes for:

- Carbon

- Aluminum

- Copper

- Tungsten

- Uranium

Solution
